- Keywords
- Questions

э

- Virtual Machine (VM)
- Popek and Goldberg (1974)

A virtual computer system is a hardware-software duplicate of a real existing computer system in which a statistically dominant subset of the virtual processor's instructions execute on the host processor in native mode.

< /₽ > < ∃ >

- Duplicate underlying hardware
 - Virtualization \neq emulation
- Run (almost) as fast as the physical machine
- Abstract hardware resources
 - CPU
 - Memory
 - I/O devices

э

-∃->

Hypervisor, Virtual Machine Monitor (VMM)

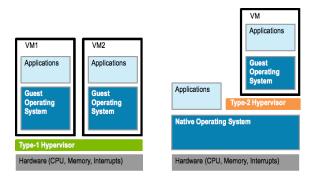

- The two often get confused in literature
- One hypervisor per physical machine
- One VMM per VM

Virtualization architectures

- Type I: Baremetal or native
- Type II: Hosted

Source: http://microkerneldude.wordpress.com

э

- Binary translation
 - Translate sensitive instructions to non-sensitive ones
 - Can run unmodified guest OSes
- Paravirtualization
 - ▶ gr. para (alongside) + virtualization
 - More efficient than binary translation
 - Also more intrusive: requires modification of guest OS
- Hardware-assisted virtualization
 - Extend CPU with special "hypervisor" state
 - Trap-and-emulate
 - Similar for memory, I/O

- Keywords
- Questions

э

- Kernel-based Virtual Machine
- Module for the Linux kernel that turns it into a hypervisor
 - Part of the Linux mainline kernel (since 2.6.20)
- Exposes /dev/kvm to user space
- Requires a user space host to run
 - ▶ e.g. QEMU

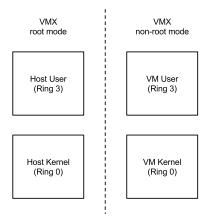

э

- kvm.ko module provides virtualization interface via /dev/kvm
- QEMU sets up the guest VM using /dev/kvm
- This requires hardware assisted virtualization (VT-x or AMD-V)
- Otherwise QEMU will fall back to software emulation
- ► KVM architecture is **strongly** dependent on Linux/x86

3) 3

- Base ISA is not virtualizable
- CPU modes/Privilege Levels:
 - User mode (PL0)
 - Supervisor mode (PL1)
 - Monitor mode (Secure PL1)
 - ▶ ...

TrustZone/Secure Monitor does not provide virtualization

- No support for trap-and-emulate logic
- Secure boot, chain of trust
- Memory isolation from a rich OS
- Running trusted/proprietary software (e.g. Digital Rights Management)

3) 3

- Extensions for CPU and MMU virtualization
- Implemented in Cortex-A15, Cortex-A7
- ▶ New processor mode: *Hyp mode* (PL3)

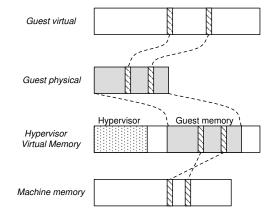

Monitor Mode (Secure PL1)

- Traps are configurable
- Sensitive instructions may trap to
 - Supervisor mode
 - Hyp mode
- Hyp mode has a reduced number of registers compared to Supervisor mode

MMU supports two stages of translation:

- Stage 1: Virtual (VA) to Intermediate Physical (IPA)
 - Managed by guest OS
- ► Stage 2: Intermediate Physical (IPA) to Host Physical (PA)
 - Managed by hypervisor

- ► KVM architecture is **strongly** dependent on Linux/x86
- Difficult to migrate Linux to Hyp mode
 - Modify a lot of code
 - Maintain separate branch
 - Don't get included in upstream
- Hyp mode lacks the features of VMX root mode
 - Difficult run an entire OS there

Factor KVM into Highvisor and Lowvisor

E

Lowvisor

- Switches between Host (Highvisor) and VMs
- Highvisor
 - Leverages KVM/Linux's mechanisms
 - Manages both its page tables and the Lowvisor's
- ▶ Note: trapping to the Highvisor requires double-switching

э

- T

- ▶ VMs and the Host/Highvisor run at the same level of privilege
- All world switches are intermediated by the Lowvisor
- The Host controls switching policy

э

-

- Direct access to I/O memory is disabled
 - Accesses by the VM will result in Stage 2 pagefaults
 - ... and trap to the hypervisor
 - Device access policy is controlled by QEMU
- Pass-through devices are an exception

- Interrupts are emulated through VGIC
- VGIC state is saved/restore on context switches
- GIC distributor accesses will trap to the hypervisor
 - Virtual distributor routes IPIs

- Uses virtual timers
- Only Hyp mode can access physical timers
- Virtual timer interrupts trap to hypervisor
 - Hypervisor forwards interrupts to VMs
 - Hypervisor performs ACK and EOI operations
- Per-CPU timers are multiplexed using the Host's software timers
